

# All about version control system

- Missing semester (MIT)

folders → "trees"  
files → "blobs" } terminology.

```
type blob = array <byte>
type tree = map <string, tree | blob>
type commit = struct {
    message
    author
    snapshot: tree
    parents: array <commit>
    (what preceded a commit)
}
```

Objects = map <string, object>

blob tree commit

objects are "Content" addressed.

key is (hash)

---

let us say we have an 'object store' to store all the objects.

To store :

```
def store(o):
    id = sha1(o)
    objects[id] = o
```

hash

To define:

```
def load(id):
```

```
    return objects[id]
```

This is git's "On disk data store".

• references: map <string, string>

both are human readable.

<hash, human\_name>

These references are 'mutable' readable

### COMMANDS

① git init initialise empty git rep

② git help command

③ git status Info on the branch, commits

④ git add ./filename/dir name etc  
Adds files to staging area

⑤ git commit  
Creates a snapshot (author, timestamp, etc)

hash (returned by git commit)

⑥ git log --all --graph --decorate --oneline  
this is the hash you get after

⑦ git cat-file -p <hash>

Gives the details of the snapshot git commit.

<hash> is the hash of the commit.

Basically you can get a hash of anything, a number, a file (beauty of hash ♥), snapshot

(in case of commit)

tree & other information

This tree further contains hashes of blobs

A useful version of git log command:  
"git log --all --graph --decorate"  
Gives a nice graphical version of git log.

⑧ git checkout branch/commit <sup>remembers it's the hash</sup>

Move around version history / previous state

\*\* This changes the references only \*\*. So  
when we use the 'git log' after checkout  
we can still see the same history.

Be careful with 'checkout' command though  
since you could be overwriting the changes  
(if not committed yet!)

⑨ git diff <file/commit/branch> # diff b/w  
eg: HEAD readme.md  
master readme.md

## BRANCHING & MERGING

⑩ git branch <name> # list the branches in the repo

git branch -vv # verbose

git branch new-br # new-br points to HEAD

git checkout -b <new-branch>

⑪ git merge <branch> checkout to master/  
previous state before.

Merge conflict \*\*

- when git can't automatically figure out  
conflict b/w parallel branches while merging them

Use git mergetool

**git Remote** Add remote repo for collaboration!

(12) **git remote**  
lists all the remotes for the current repo.

**git remote add** <origin> <url>

tell the local repo that

Commands to interact with this repo:

(1) **git push** <remote> <branch>

(2) **git clone** <url> <folder name>

(3) **git branch** --set-upstream-to =<name>/<branch>

(advanced)

→ set up to which branch (in the remote repo) to refer (track)

eg. So you can push without additional args like **git push** <origin> <master>

(4) **git fetch** # retrieve changes from remote to local repo

(5) **git pull** → **git fetch**  
→ **git merge** → retrieve and merge to local repo.

(13) **git config** # you can add some personal info.  
# can configure any way (eg. add documentation)

(14) **git clone** <- shallow> # clone from a remote repo

Commands that are handy but not sure if I'll ever use!

(15) **git blame** <file> # see who edited what!!

⑬ git show <commit> #info on the commit.  
git stash #save the work but revert to  
the previous stage.  
git stash pop #undo the stash.  
git bisect (advanced)  
#basically to debug.

⑭ git ignore

- ignore some set of files
- useful to specify patterns of files you want to ignore.

(1:22:00 onwards)
